Potential health risk by contaminants prevents recycling!

Recycling back to Food
Packaging Material: **only
possible for PET bottles!**

Table 2: TTC values – classification of substances

Classification	Worst Case Assumption	TTC value in µg/person per day
Potential DNA-reactive mutagens and/or carcinogens		0.15
Organophosphates and carbamates		18
Cramer Class III		90
Cramer Class II		540
Cramer Class I		1,800

EFSA Scientific Committee. (2019). Guidance on the use of the Threshold of Toxicological Concern approach in food safety assessment. EFSA Journal, 17(6), e05708.

Possible contaminations in recycled materials

Contaminants during recycling,
sorting & cleaning

Additives of high grade plastic

Additives of normal plastic

Original NIAS of recycled plastic

Components from food into
packaging
Flavour compounds, substances from food,
food additives

Degradation products during recycling

Contaminants intended use
(e.g. pesticides)

Current EFSA Assumption:

- All input material for recycling is contaminated with DNA-reactive carcinogens!
- None of the evaluated Polyolefin Recycling Processes is sufficient to prevent critical levels of DNA-reactive carcinogens

Cramer Class I	1,800

Ames Test

© Wikipedia

- + Sensitive and robust
- + Broad acceptance (OECD Guidelines)
- + Focus on direct DNA-reactive substances
- Labour intensive
- Space consuming

Miniaturized Ames Test (Ames MPF)

- Cultivation and exposure in liquid medium
- Colorimetric readout
- Higher throughput (microtiter plates)
- + Lower sample amounts required
- + Less incubator space required

> 100 recycled plastic samples analysed!

Recycled Plastics

□ n.a. ■ + ■ - ■ equivocal

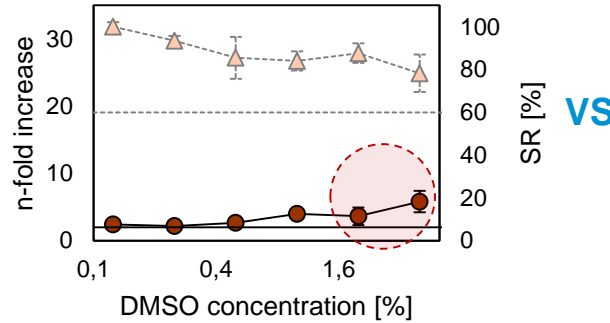

Some polyolefin recyclates score strongly positive!

—●— n-fold increase - - - - 2-fold increase —○— SR [%] - - - - - 60% SR

Recycled polyolefin

Mutagenic reference oil (positive control)

Mutagenic reference sample (for inter-lab study)

Some recycled polyolefins have strong positive effects in the Ames test, partially even higher than in mutagenic reference oils or intentionally spiked FCM samples.

However: Recycled PET scores negative in the Ames test.

Some polyolefin recyclates score strongly positive!

—●— n-fold increase - - - - 2-fold increase —○— SR [%] - - - - - 60% SR

Recycled polyolefin

Mutagenic reference oil

Mutagenic reference sample

High mutagenic activities could only be explained by alarmingly high concentrations of known mutagens such as primary aromatic amines or nitrosamines.

Mutagenic activity refers to the activity of a Primary Aromatic Amines or Nitrosamines in concentration of > 100 mg/L!

Some recycled polyolefins have strong positive effects in the Ames test, partially even higher than in mutagenic reference oils or intentionally spiked FCM samples.

However: Recycled PET scores negative in the Ames test.

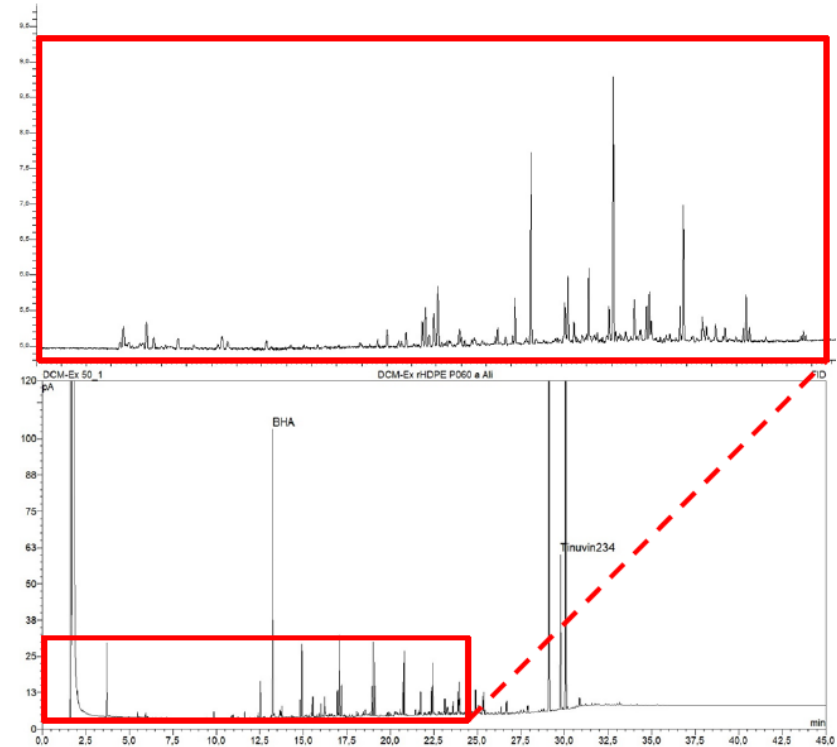

Standard screening

Non-target GC-MS screening

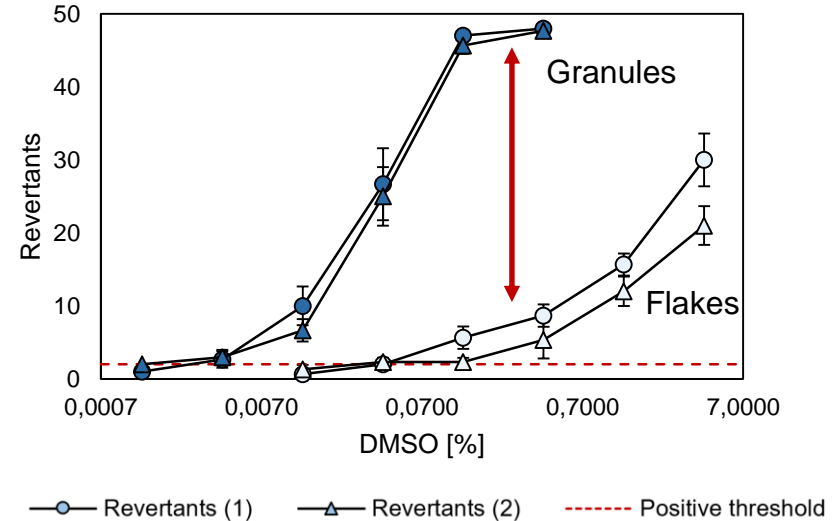

DNA-reactive substances not detectable by standard GC-MS non-target screenings!

Primary Aromatic Amines detected in Target Screenings

Signal intensity increases during processing

Granules show higher mutagenicity signals than corresponding flakes. This indicates that Ames positives substances might be mainly formed during treatment steps in the extruder.

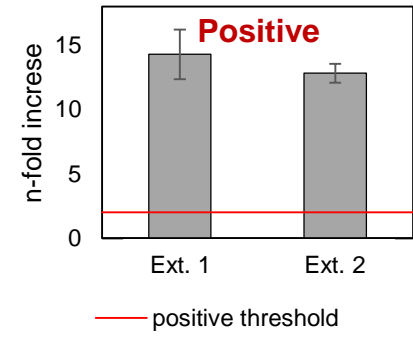

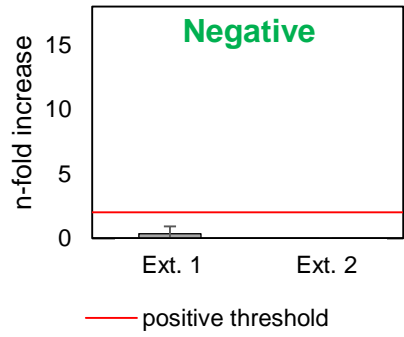

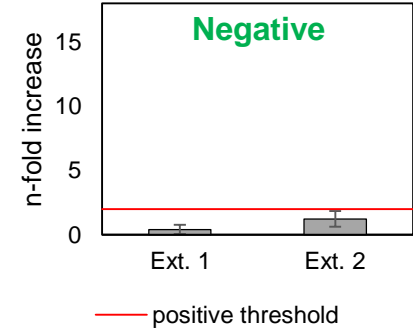

Only **printed AND recycled** materials scored Ames positive!

Unprinted foil

Printed foil

Recycling process

Recycling process

rPP from white printed materials

- Nitrocellulose (M1)
- Nitrocellulose (M2)
- Polyurethane (M1)
- Polyurethane (M2)
- Polyvinyl butyral (M1)
- Polyvinyl butyral (M2)
- Positive threshold

rPP recyclates were produced from white printed input streams.

Printing inks based on:

- Nitrocellulose (NC)
- Polyvinyl butyral (PVB)
- Polyurethane (PU)

Recyclates from nitrocellulose-based printed samples are strongly Ames positive.

Nitrocellulose based Inks are not the only challenge for recycling

Recycled Polyurethane based Inks: No systematic mutagenic activity
 BUT: mutagenic activity in some recycled multicolor PU based inks.

Multicolor PU-printing ink,
 recycled

VS

White PU-printing ink,
 recycled

Nitrocellulose is not the only risk factor!

More research required to closer identify other risk factors (pigments?)

- DNA-reactive substances have 120-fold lower safety threshold than any other substance group - EFSA authorization depends on the residual DNA-reactive substances in recyclate!
- Systematic introduction of DNA-reactive contaminants in some recycled flexible packaging
- Recycling of nitrocellulose-based printing inks correlated with the formation of DNA-reactivity.
- Nitrocellulose is not the only risk factor for recycling of printed packaging
 - Other printing ink types can also lead to mutagenic activity after recycling – but less systematic (connection to specific pigments/color shades?)

No DNA-reactive contaminants detected in food-grade recycled plastic (PET)!

- Efficient De-Inking Processes or a “Design-for-Recycling” for Inks in FCM could help to improve the safety of recycled printed packaging
